

## From Latent to Deep Latent Variable Models

A Study On Causal Effect Inference with CEVAE

Valeria De Stasio, Christian Faccio, Giovanni Lucarelli June 17, 2025

#### Objective: estimating causal effects

Estimate how a medical treatment *T* affects the health *Y* of a *random* patient.

$$P(Y = y | do(T = t)) = P(Y = y | T = t)$$

$$ITE = \mathbb{E}[(Y | do(T = 1)] - \mathbb{E}[(Y | do(T = 0)]]$$

This is usually the case in a randomized controlled trial (RCT), where the treatment is randomly assigned to the patients.

1

#### Confounder

In a observational study:

no control over the treatment T assignment

 → there may be a confounder X (e.g. Income) that influences
 both variables

$$P(Y|do(t)) \neq P(Y|t)$$
 $P(Y|do(t),x) = P(Y|t,x)$ 

Treatment (T)

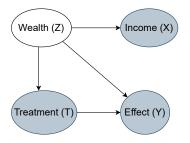

Effect (Y)

If the confounder is observed even a linear rergession can do the job!

2

#### Latent confounder

But what if the confounder *Z* (e.g. Wealth) is **not** observed and the observed *X* is only a proxy of it?

Idea: estimate the latent variable and condition on it

3

#### Vanilla Latent Variable Model

Assume parametric relationships between variables

$$Z \sim \mathcal{N}(0, 1)$$
 $X_j \sim \mathcal{N}(az + b, \operatorname{diag}(\sigma_X^2))$ 
 $T \sim \operatorname{Be}(\sigma(cz))$ 
 $Y \sim \mathcal{N}(et + fz, \sigma_Y^2)$ 

- · Infer parameters using Mean Field Variational Inference
- For a new data point x:
  - infer:  $z_0 = \mathbb{E}[Z|X, T = 0], z_1 = \mathbb{E}[Z|X, T = 1]$
  - compute ITE =  $\mathbb{E}[Y|T=1,z_1] \mathbb{E}[Y|T=0,z_0]$
- · Problem: we need to train a new model at test time!

#### Deep Latent Variable Model: CEVAE

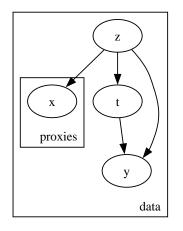

- Assume parametric relationships between variables through Neural Networks
- **CEVAE** = VAE + causal semantics for latent Z

$$(X, T, Y) \longrightarrow Z \longrightarrow (X, T, Y)$$

 Counterfactuals in one forward pass ⇒ amortized inference, no test-time training

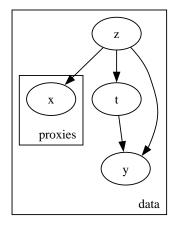

#### Synthetic linear dataset

$$Z \sim \mathcal{N}(0,1)$$
  
 $a_j \sim \mathcal{U}(-10,10)$   
 $X_j \sim \mathcal{N}(a_j z, \sigma_X^2)$   
 $T|Z \sim \text{Be}(\sigma(\beta z))$   
 $Y|T, Z \sim \mathcal{N}(z + t, \sigma_Y^2)$ 

**Remark:** ITE is constant for all x!

#### Synthetic non linear dataset

$$Z \sim \mathcal{N}(0,1)$$

$$a \sim \mathcal{U}(-10,10)^d$$

$$X_1, ..., X_d \sim \mathcal{N}(a \tanh(z), \sigma_X^2 \mathbb{I})$$

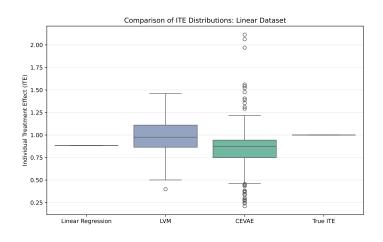

$$T|Z \sim \text{Be}(\sigma(\beta z))$$

$$Y|T, Z \sim \mathcal{N}\left(\text{NonLin}(z,t), \sigma_Y^2\right)$$

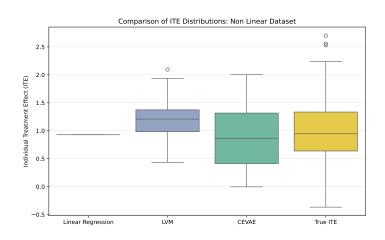

$$\text{NonLin}(z,t) = \sin(z) + \frac{1}{2}z + t\left(1 + \frac{1}{2}z\right)$$

**Remark:** ITE depends on interaction between t and z!

## Results (1/2): Linear Dataset

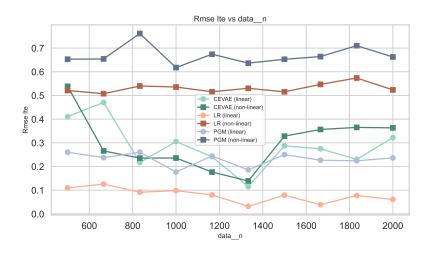

# Results (2/2): Non Linear Dataset

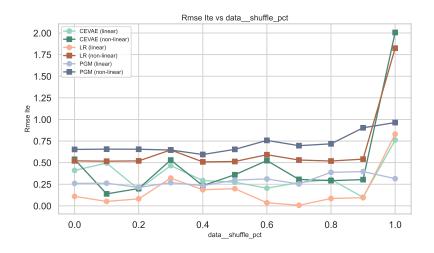

# Internal Representation: Linear Dataset

# Internal Representation: Non Linear Dataset

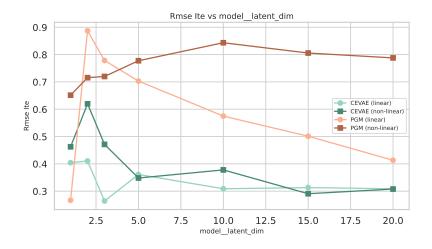

# Experiment 1: Increasing the sample size

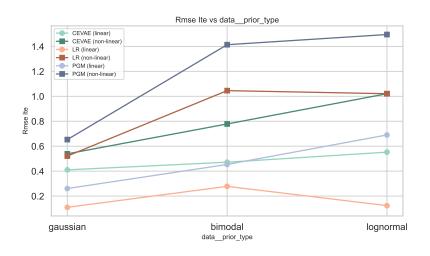

# Experiment 3: Increasing decorrelation among proxies

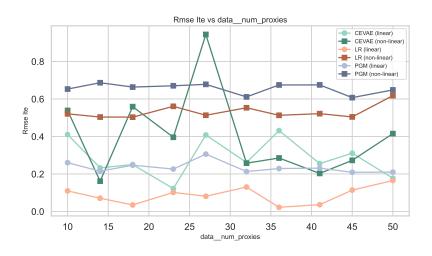

## Experiment 4: Increasing latent dimension

## Experiment 5: latent distribution misspecified

## Experiment 6: Increasing the number of proxies

#### **Conclusions**

#### Pros

- Captures non-linear causal links
- Counterfactuals in one forward pass
- Fewer hand-crafted assumptions

#### Cons

- Computationally intensive training
- Sensitive to the hyperparameters
